Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description

This invention relates to transducers, in particular to a scanning ultrasonic transducer.

Transducers, and in particular ultrasonic transducers, are utilized in many applications, such as medical imaging, where high precision is required. Particularly when the transducers are being used for medical imaging, an error in the positioning of the transducer when readings are being taken could lead to a false diagnosis or treatment. FDA regulations also limit the acoustic power output which may be utilized for imaging various areas of the body and various classes of patient such as fetal or infant. Precise control of power output is therefore required, particularly for transducers which are to be used for more than one class of imaging.

Heretofore, control of transducer position to a selected level of precision has been achieved by maintaining high tolerances in the manufacturing process and by carefully testing and hand-adjusting transducer units which do not conform to these tolerances. For example, mechanical scanning transducers typically have a position sensor, the output from which is compared with a reference signal, and the error output from the comparator is utilized to control a servo-motor which moves the transducer through its scan path. Any nonlinearity in the position sensing device can result in false position readings and can also cause slight variations in the sweep speed of the transducer. Even when great care and expense are taken in the manufacturing process and in the hand adjustment of the device, it is impossible to eliminate all nonlinearity from the position sensing mechanism. As a result, such transducers have been relatively expensive while still providing less than ideal operation.

Similarly, the power output characteristics of individual transducer elements may vary slightly with the applied input, making it difficult, even with high manufacturing tolerances, to provide transducers which produce required acoustic power outputs for different classes of service. Again, even at relatively high cost, less than ideal results are achieved.

Since, either because of FDA regulations, or for other reasons, certain transducers may not be suitable for certain classes of service, it would be desirable if a means could be provided to inhibit the use of such transducers for such classes of service. Existing transducers do not generally provide such a capability.

Another problem with existing transducers is that each transducer has various constants and other parameter values which must be known to the system utilizing the transducer in order for the system to properly control the transducer and to

properly interpret the results obtained therefrom. Heretofore, the system utilizing the transducer has had to store representative values for each class of transducer which might be utilized with the system and select the appropriate values from an identification of the class of transducer being used with the system at any given time. This information as to the class of transducer being used may either be inputted manually or may be read from a simple data storage element included with the transducer.

This procedure suffers from a number of limitations. First, while the various constants and other values which are stored are substantially uniform for a given class of transducer, there may be substantial variations in these values among individual transducers in the class. Thus, while the stored values may be usable for all transducers of a class, they are not the exact values for the particular transducer being utilized at any given time. Differences between the average stored values and the actual values for the transducer being utilized may result in erroneous outputs in some applications.

Further, over the years that an ultrasonic system is utilized, new classes of transducers will become available, the parameters for which are not initially stored in the system. This necessitates a reprogramming of the system which includes either firmware or software changes for each new transducer or family of transducers which are provided for use with the system. Software media and/or documentation must therefore be provided with each new release of transducer to permit appropriate updating of the systems in which the transducers may be utilized.

Another potential problem with existing transducers is that, to the extent there are any records at all on use of a transducer, such records are normally manually maintained. Since the transducer used in a given system may be varied for varying applications, it may be difficult or impossible to determine the period that a given transducer has actually been used. Thus, there is normally no record of the actual number of hours of use for a given transducer. Such information could be useful in determining when a transducer should be replaced, when preventive maintenance should be performed, or for other service or related purposes. Such information would also permit service histories on transducers or classes of transducers to be developed which could be used for various purposes.

Finally, no current mechanism exists for informing the ultrasonic or other transducer system on the full range of operating parameters for a given transducer, such as its type, model number, serial number, and various advertised and actual characteristics such as frequency, maximum scan

angle, focal distance and the like.

It is therefore an object of this invention to provide a relatively simple and inexpensive mechanism for use in transducer systems for assuring positional accuracy, uniform scan rate and proper power output from the transducer element while at the same time reducing manufacturing tolerances for the transducer.

A more specific object of this invention is to provide an ultrasonic transducer system which is capable of compensating for nonlinearity in the position sensing mechanism so as to permit accurate positioning of the transducer element and a uniform scan rate for the element.

Another object of this invention is to provide a mechanism for providing to a transducer system accurate information concerning the operating characteristics and constants of the transducer being utilized in the system without requiring any reprogramming of the system.

Still another object of this invention is to provide a simple mechanism for keeping track of such things as the age of a transducer element, the actual period of use for the transducer, the period of use for various classes of service, the period of use since last maintenance, and the like.

In U.S-A-4587971 there is disclosed a servo-controlled scanning transducer system having a transducer element for scanning means for sensing the position of the element in its scan path and means responsive to the position sensed by said sensing means for controlling the movement of said element, said means for controlling including means for generating a reference signal, means for comparing the position sensed by said position sensing means at a point in time with the reference signal for the corresponding point in time, and means responsive to a difference output from said means for comparing for controlling the scanning of the transducer element, and means for compensating for errors in transducer element scanning which comprises memory means for storing correcting information for said errors. The disclosure of this document corresponds to the introductory part of claim 1.

Document JP-A-60 60507 discloses a device with a correction error storage circuit for correcting an error of a position detector.

Document EP-A-0079086 discloses a sensor for monitoring a chemical, physical or biological parameter and including a memory unit in the sensor housing or in a connector.

According to the present invention, there is provided a scanning transducer system having a transducer element for scanning, means for sensing scanning information relating to the element and means responsive to the scanning information sensed by said sensing means for controlling op-

eration of said element, and means for compensating for errors in transducer element scanning which comprises memory means for storing correcting information for said errors, characterised in that the memory means is integral with the transducer element, and is at least selectively erasable, and in that said means for controlling includes processing means for utilising the information stored in said memory means to modify the output from said means for controlling to compensate for said errors, said processing means also periodically updating said information.

The scanning information preferably concerns the position of the element in its scan path, and said controlling means is responsive to the position sensed by said sensing means to control movement of the element.

The error information stored in the memory means may be utilized to modify positions stored in a position table which table is utilized to control the point at which readings or other actions are taken by the transducer. For example, the table could control the points at which ultrasonic lines are generated. The stored error information can also be used to modify the reference signal utilized to control the servo-movement of the transducer element, thus providing for a substantially uniform scan rate of such element.

In a preferred embodiment, the transducer element is mounted in a head which is connected through a cable to connector which connects to the remainder of the transducer system and the memory means is mounted in the connector.

The memory means may also store an indication of a selected output signal characteristic, such as the output signal power, from the transducer element for selected conditions, the system including means for utilizing the output signal characteristic indications stored in the memory means to control the selected output signal characteristic from the transducer element. The memory means may also include a field-of-use control indication, the system having a means responsive to the field of use control indication for limiting the fields of use for the transducer.

The memory means may be at least selectively erasable and means may be provided for storing in the memory means selected information concerning the operation of the transducer element such as for example the duration of service thereof. Various other selected information concerning the transducer such as, for example, various operating constants, may also be stored in the memory means which is mounted with the transducer element.

The foregoing and other objects, features and advantages of the invention will be apparent from the following more particular description of a preferred embodiment of the invention as illustrated in

the accompanying drawings.

In the Drawings:

Fig. 1 is a semi-schematic partially cut-away view of a transducer system of a preferred embodiment of the invention.

Fig. 2 is a schematic diagram of a transducer system of this invention.

Fig. 3 is a diagram illustrating ideal and actual voltages at various points in the circuit of Fig. 2.

Detailed Description:

Fig. 1 is a semi-schematic representation of a scanning mechanical ultrasonic transducer system utilizing the teachings of this invention. The transducer system includes a transducer head 10, a cable 12 leading from head 10 to the plug 14 of a connector 16 and system circuitry 18 connected to the socket 22 of connector 16. Head 10 has a main body or casing 24 to the top of which is secured a transparent cover 26. In the figure, cover 26 is shown secured to body 24 by screw joint 28. The sealed cavity 30 formed within cover 26 is normally filled with an acoustic coupling fluid having an acoustic impedance substantially matching that of the object being imaged.

Mounted within the cavity 30 is a transducer element 32 which is adapted to alternately generate and receive ultrasonic acoustic signals. Element 32 is attached to a base 34 which is mounted in the cavity to be pivoted about shaft 36. A flexible member such as a spring, wire or cord 38 wraps at one end around a pulley 40 attached to base 34 and is attached to the pulley. The other end of member 38 is attached to servo-motor 42 which is mounted in casing 24. Movement of motor 42 is transmitted through member 38 to rotate base 34 and transducer element 32 mounted thereto in one direction, and to control the return of these elements in the opposite direction.

A vane or fin 44 is attached to the underside of base 34, the vane being wider on one side than on the other and varying in width (radius) between the two ends in a predetermined manner (such as, for example, a section of a spiral). Vane 44 travels through a slot in a toroidal inductor 46 causing predetermined variations in the inductance thereof which varies as a function of the angular position of transducer element 32. Ideally, the inductance of inductor 46 varies linearly with the angular position of the transducer element. However, as has been previously discussed, this objective is not easily achievable and the output from the toroidal inductor is therefore generally, at least to some degree, nonlinear.

Positioned in connector plug 14 is a memory device 50. This may be a programmable read-only memory (PROM) but is preferably an erasable PROM (EPROM). For a preferred embodiment, memory device 50 is an electrically erasable PROM (EEPROM). An EEPROM may be digitally addressed and accessed in the same manner as a random access memory and may have information erased and rewritten in any and all of its memory locations. Memory 50 is electrically connected by for example pins 52 to system circuitry 18.

Fig. 2 is a general schematic diagram of the system of this invention. Included as part of system circuitry 18 is a processor 60 which may, for simpler applications, be a standard microprocessor. For more complex applications, the processor 60 may be a minicomputer. Processor 60 receives certain information which will be described in greater detail hereinafter from memory device 50 and utilizes such information in conjunction with other information applied thereto to control, among other things, the scanning of and output power from transducer element 32. In particular, processor 60 generates the reference signal to be used for control of servo-motor 42 and stores a digital representation of such signal in reference signal store 62. This information is periodically read out and applied through digital to analog converter 64 as one input to comparator 66. The other input to comparator 66 is the output from position sensor 68. Position sensor 68 includes inductor 46 and vane 44, the output being from inductor 46. The output from comparator 66, which may, for example, be part of system circuitry 18, is a voltage which is proportional to the difference between the actual position of transducer element 32 and the desired rotational position of this element. This signal is applied to control servo-motor 42. The elements 62-68 and 42 operate in a standard manner to cause transducer element 32 to be rocked back and forth about pivot 36 at a frequency and otherwise in accordance with the reference signal stored in reference signal store 62.

Similarly, processor 60 generates and stores in position store 69 a table of voltage values from position sensor 68 which correspond to transducer positions in its scan path at which readings or other desired actions are to be taken. This information is periodically read out and applied through D/A converter 71 as one input to comparator 73. The other input to comparator 73 is the output from position sensor 68. The output from comparator 73 is applied to trigger transducer element 32. Except as hereinafter discussed, the nature and operation of this triggering circuit is also conventional.

Processor 60 also determines the power level output from transducer 32 and stores a digital indication of the desired power level in power level

store 70. The output from power level store 70 is applied through digital to analog convertor 72 to control the power level output from transducer element 32.

Memory 50 may have a number of different storage areas. While separate lines have been shown leading from each storage area to processor 60, it should be understood that the memory 50 may be addressed from the processor and the output from all areas thereof applied through a common output bus. For purposes of illustration, memory 50 is shown as having an area 80 which stores information concerning nonlinearity errors in position sensor 68, an area 82 which stores power tables used for controlling the power output of transducer 32, and an area 84 for storing general information concerning the transducer such as its type, model number, serial number, advertised and actual measured operating frequencies, advertised and actual focal distance and the like. Area 82 may contain a field-of-use or class-of-use control byte 83 which may be used to inhibit the transducer from being used for selected uses for which it is not suitable. Area 84 may also store certain constants used in connection with operating the transducer and interpreting the results thereof. While the areas 80-84 of memory 50 may be stored in an EEPROM, it is contemplated that the information in these areas of memory would be read only.

Finally, memory 50 has an area 86 which stores various information concerning the duration of use of the transducer, such as total hours of actual use, hours of use since last maintenance, hours of use for various classes of service, or the like. Entries in this area of memory would be periodically erased and rewritten as the transducer is used. Various other information may also be recorded in this area of memory.

Operation:

As previously indicated, ideally, the output from position sensor 68 varies as a direct linear function of the angular position of transducer element 32. This is illustrated by line 100 in Fig. 3 which shows the voltage increasing linearly as inductance is reduced as a result of element 32 being moved through, for example, an angle of 60 degrees in a counter-clockwise direction from its extreme position facing to the right of center as shown in Fig. 1 to the extreme position facing to the left of center as seen in this figure. However, due to nonlinearities in the position sensor device, the actual output from the position sensor may in fact vary nonlinearly as shown for example by the line 102. It should be emphasized that the line 102 is shown for purposes of illustration only and the nonlinearity may take any form. For example, the nonlinearity

may all be in one direction, the actual curve may follow the ideal curve for some portion of the scan path, and there may be one or more crossovers which occur at any point along the scan path. Regardless of the form the nonlinearity takes, if, for example, it is desired that readings or other action be taken at the points A-I along the path of travel of transducer element 32, the nonlinearity in the position indication from sensor 68 may cause one or more of these readings to be taken at the wrong point in the scan path and may result in uneven spacing between successive readings. Thus, for example, processor 60 would cause the reading at point C in the scan path to occur when the voltage level from position sensor 68 is at level X. However, due to the nonlinearity in the output from the position sensor, it is seen that voltage X is achieved on line 102 when the transducer element is in fact at point C' in its scan path, C' being a point in the scan path somewhat earlier than the point C. Taking a reading at this point in the scan path would thus cause the results from the ultrasonic imaging to be at best distorted and at worst erroneous.

In accordance with the teachings of this invention, as part of a final step in the assembly of the transducer consisting of head 10, cable 12 and plug 14, the actual output from position sensor 68 at selected points in the scan path, for example at every half degree of rotation through the scan path, is measured and the actual or incremental deviation of this value from the desired value, represented by the line 100, at that point in the scan path is stored in area 80 of memory 50. As previously discussed, processor 60 initially stores a table with the voltage values from position sensor 68 at which each reading or other desired action is to be taken in position table store 69. When plug 14 is mated with socket 22, processor 60 reads the contents of area 80 of the memory 50 for the transducer and utilizes the deviation value stored for each point in the scan path at which a reading is to be taken to modify the voltage value in the table in store 69 for that point so that readings in fact occur at precisely the right positions in the scan path for the transducer being utilized. Thus, at the point C, the deviation (d) would be added to the value X stored in the table so that for this transducer, the reading at position C would occur when the output from position sensor 68 was equal to a voltage of (X+d). The system is thus able to use position sensors with lower tolerances while still achieving a very high level of linearity in the operation of the system.

From Fig. 2, it is seen that the output of position sensor 68 is also utilized to control the movement of servo-motor 42. Thus, the nonlinearity in the output of position sensor 68 can also

cause nonlinearities in the movement of the servo-motor resulting in the scan rate of transducer element 32 being non-uniform and in uneven spacing between the points, such as the points A-I, where readings or other action is taken.

In accordance with the teachings of this invention, the above problem is dealt with by modifying the reference signal stored in store 62 in a manner equal and opposite from that of the nonlinearity in the position signal from sensor 68.

More specifically, referring to Fig. 3, the reference signal for the sweep in one direction may, for example, have the shape of curve 104 in Fig. 3. In order to compensate for the nonlinearity in the position signal from sensor 68, processor 60 utilizes the deviation information in area 80 of memory 50 to modify the reference signal stored in store 62 to, for example, the reference signal 106 shown in Fig. 3 so that the inputs to comparator 66 result in uniform drive signals to servo-motor 42.

As previously indicated, the output audio power from transducer element 32 will vary slightly from transducer element to transducer element for a given potential input to the transducer from converter 72. Since the output power from the transducer for various classes of service is tightly controlled by the FDA, and in order to avoid potential harm to a patient, it is important that the actual output power correspond very closely to the desired output power. Transducers in the past have frequently operated below optimum power to avoid any possibility of excessive output from a given transducer element.

In accordance with the teachings of this invention, the actual power output from the transducer element 32 used in a given transducer is measured for selected inputs at a final stage in the manufacture or testing of the transducer and this information is stored as a power table in area 82 of memory 50 for the transducer. When the transducer is connected to system circuitry 18, processor 60 reads the information from the power table for the transducer into its own memory and utilizes that information to store the appropriate power level value in store 70 for a desired power level output from transducer 32.

If a particular transducer is not designed for particular modes of use or classes of service, byte 83 in area 82 may be appropriately set. This byte is detected by processor 60 and utilized by the processor to inhibit the use of the transducer for the prohibited classes of service. For example, if the transducer is not suitable for use for fetal scanning, the byte 83 would indicate that this class of service was prohibited and would be stored in an appropriate location in processor 60. If the processor was advised that the system was to be used for fetal scanning, it would check the contents

of this byte in its memory and if the byte indicated that such scanning was not permitted for the transducer, the processor would inhibit the use of the system for such scanning, until the transducer was replaced.

At the same time that the information in areas 80 and 82 of memory 50 are read into the memory of processor 60, the various items of general information and constants stored in area 84 of the memory would also be read into processor 60. These values would be used by the processor as appropriate in operating the system or in interpreting the results thereof. They might also be used for service or other purposes. The values stored and used are in each instance the correct values for the particular transducer being utilized. Further, this information is available to the system for new classes of transducers or even an experimental transducer which is to be used with the system without requiring that the system be reprogrammed as each new class of transducer comes on the market. It is therefore much quicker and easier to introduce new types of transducers.

Finally, area 86 of the memory is adapted to store selected information concerning the operation of the transducer. The information which is initially stored in this area of memory 50, which may initially be completely blank, is read into an appropriate area in the memory of processor 60. This information is then updated by the processor to reflect operation of the transducer and is periodically written into the appropriate position in area 86. For example, processor 60 may maintain a running tally of the duration of use of the transducer and may read the current setting of this tally into the appropriate location in area 86 at the end of each session, or at other selected times. In any event, such information would be read into memory 50 before the units were turned off so that connector 16 could be open, thereby assuring that if the transducer is disconnected from the system circuitry 18, area 86 of memory 50 will contain current information concerning the operation and use of the transducer.

While in the discussion above, the invention has been shown utilized in connection with a mechanical ultrasonic scanning transducer, it is apparent that the principles of this invention could be utilized with phased array ultrasonic transducers or with other transducers which require precision of scan location or output and where the controls for positioning and/or output may vary from unit to unit. It may also be used in transducer applications when there is a need to keep a running tally of some aspect of the operation or use of the transducer.

Further, while for the preferred embodiment, memory 50 has been shown located in plug 14 of

connector 16, it is apparent that the memory device 50 could be located at any appropriate location in the transducer assembly consisting of head 10, cable 12 and plug 14. Factors in selecting the location are available space, ability to make connections and length of connection. Thus, while the memory device must be mounted integrally with transducer element 32, the precise location in the transducer assembly where it is located is not critical.

In addition, while memory 50 has been shown as having areas 80-86 for the preferred embodiment, the memory 50 used for a particular application might have any one or more of these areas or might have one or more areas storing different information as required for the application.

Further, while for the preferred embodiment the error being compensated for was a nonlinearity in the position sensing device used with the servomotor, it is apparent that the teachings of this invention could be utilized to compensate for any measurable error which might arise in the mechanism for controlling the movement or scan position of the transducer, including, but by no means limited to a nonlinearity in the sensor itself, or the like. Similarly, while, for the preferred embodiment, it is the power output of the transducer element which is being controlled, the teachings of this invention could also be utilized to compensate for variations among transducer elements in some other characteristic or aspect of the transducer output such as, for example, frequency.

Claims

1. A scanning transducer system having a transducer element (32) for scanning, means (68,44,46) for sensing scanning information relating to the element and means responsive to the scanning information sensed by said sensing means for controlling operation of said element, and means for compensating for errors in transducer element scanning which comprises memory means (50,80) for storing correcting information for said errors, characterised in that the memory means is integral with the transducer element, and is at least selectively erasable, and in that said means for controlling includes processing means (60) for utilising the information stored in said memory means to modify the output from said means for controlling to compensate for said errors, said processing means also periodically updating said information.
2. A transducer system as claimed in claim 1, wherein the scanning information concerns the position of the element (32) in its scan path,

and said controlling means is responsive to the position sensed by said sensing means (68, 44,46) to control movement of the element.

3. A transducer system as claimed in Claim 2, wherein the errors in transducer element scanning are caused by nonlinearity in the means for sensing the position; and wherein said memory means (50,80) stores a measured error for said position sensing means at selected points in said scan path.
4. A transducer system as claimed in Claim 3, wherein said means for controlling includes means (69) for storing a table of selected positions in said scan path; and wherein said processing means (60) includes means for utilizing the errors stored in said memory means (50,80) to modify the positions stored in said table.
5. A transducer system as claimed in Claim 4, wherein comparing means (73) are provided for triggering said transducer element (32), said comparing means (73) comparing outputs from said storing means (69) and said position sensing means (68).
6. A transducer system as claimed in any preceding Claim, and further comprising a head (10) containing said transducer element (32), an electrical connector (16) for connecting the transducer element to other circuitry (18) and a cable (12) connecting said head and connector and wherein the memory means (50) is mounted in the electrical connector (14).
7. A transducer system as claimed in any preceding Claim wherein said transducer element (32) generates an output signal as it scans, and said memory means (50,82) stores an indication of a selected output signal characteristic from said transducer element for selected conditions; and including means (70) for utilizing the output signal characteristic indications stored in said memory means to control the selected output signal characteristic from said transducer element.
8. A transducer system as claimed in any preceding Claim including a field-of-use control indication (83) stored in said memory means (50,82) the processing means (60) being responsive to the field of use control indication for limiting the fields of use for the transducer.
9. A transducer system according to any preceding claim wherein said memory means

(50,84,86) stores additional information concerning the operation of said transducer element.

10. A transducer system according to any preceding Claim, wherein the transducer element (32) is a scanning ultrasonic transducer.

Patentansprüche

1. Abtastendes Wandlersystem mit einem Wandlerelement (32) für das Abtasten, einer Vorrichtung (68, 44, 46) zum Abfühlen der das Element betreffenden Abtastinformation und einer auf die von der Fühlervorrichtung abgefühlte Abtastinformation ansprechende Vorrichtung zum Steuern des Betriebes des Elementes, und einer Vorrichtung zum Ausgleichen von Fehlern beim Abtasten mit dem Wandlerelement, die eine Speichereinrichtung (50, 80) zum Speichern von Korrekturinformationen für die Fehler aufweist, dadurch **gekennzeichnet**, daß die Speichereinrichtung in das Wandlerelement integriert ist und zumindest wahlweise löschar ist, und daß die Vorrichtung zum Steuern eine Verarbeitungseinrichtung (60) aufweist, die die in der Speichereinrichtung gespeicherte Information verwendet, um den Ausgang von der Vorrichtung zum Steuern zu modifizieren, um die Fehler auszugleichen, wobei die Verarbeitungseinrichtung auch die Information periodisch aktualisiert.
2. Wandlersystem nach Anspruch 1, bei dem die Abtastinformation die Position des Elementes (32) in seinem Abtastpfad betrifft, und die Steuervorrichtung auf die von der Fühlervorrichtung (68, 44, 46) abgefühlte Position anspricht, um die Bewegung des Elementes zu steuern.
3. Wandlersystem nach Anspruch 2, bei dem die Fehler beim Abtasten mit dem Wandlerelement durch eine Nichtlinearität in der Vorrichtung zum Abfühlen der Position verursacht sind, und bei dem die Speichereinrichtung (50, 80) einen gemessenen Fehler für diese Positions-Fühlervorrichtung bei ausgewählten Punkten im Abtastpfad speichert.
4. Wandlersystem nach Anspruch 3, bei dem die Vorrichtung zum Steuern eine Einrichtung (69) zum Speichern einer Tabelle mit ausgewählten Positionen im Abtastpfad aufweist, und bei dem die Verarbeitungseinrichtung (60) eine Vorrichtung zum Verwenden der in der Speichereinrichtung (50, 80) gespeicherten Fehler aufweist, um die in der Tabelle gespeicherten

Positionen zu modifizieren.

5. Wandlersystem nach Anspruch 4, bei dem eine Vergleichervorrichtung (73) zum Triggern des Wandlerelementes (32) vorgesehen ist und die Vergleichervorrichtung (73) Ausgangssignale von der Speichereinrichtung (69) und der Positions-Fühlervorrichtung (68) vergleicht.
6. Wandlersystem nach einem der vorangehenden Ansprüche, mit ferner einem Kopf (10), der das Wandlerelement (32) enthält, einem elektrischen Stecker (16) zum Verbinden des Wandlerelementes mit einem anderen Stromkreis (18) und einem Kabel (12) zum Verbinden des Kopfes und des Steckers, wobei die Speichervorrichtung (50) in den elektrischen Stecker (14) eingebaut ist.
7. Wandlersystem nach einem der vorangehenden Ansprüche, bei dem das Wandlerelement (32), während es abtastet, ein Ausgangssignal erzeugt, und die Speichereinrichtung (50, 82) eine Angabe über eine ausgewählte Ausgangssignal-Kenngröße von dem Wandlerelement für ausgewählte Bedingungen speichert, und mit einer Vorrichtung (70) zum Verwenden in der Speichereinrichtung gespeicherten Angaben über die Ausgangssignal-Kenngröße, um die ausgewählte Ausgangssignal-Kenngröße von dem Wandlerelement zu steuern.
8. Wandlersystem nach einem der vorangehenden Ansprüche, mit einer in der Speichereinrichtung (50, 82) gespeicherten Einsatzbereichs-Steuerangabe (83), wobei die Verarbeitungseinrichtung (60) auf diese Einsatzbereichs-Steuerangabe anspricht, um den Einsatzbereich des Wandlers zu begrenzen.
9. Wandlersystem nach einem der vorangehenden Ansprüche, bei dem die Speichereinrichtung (50, 84, 86) zusätzliche Information speichert, die den Betrieb des Wandlerelementes betrifft.
10. Wandlersystem nach einem der vorangehenden Ansprüche, bei dem das Wandlerelement (32) ein abtastender Ultraschallwandler ist.

Revendications

1. Système formant transducteur de balayage comportant un élément transducteur (32) pour exécuter un balayage, des moyens (68,44,46) pour détecter une information de balayage

concernant cet élément et des moyens répondant à l'information de balayage détectée par lesdits moyens de détection pour commander le fonctionnement dudit élément, et des moyens pour compenser des erreurs lors du balayage exécuté par l'élément transducteur et qui comprennent des moyens de mémoire (50,80) pour mémoriser une information de correction pour lesdites erreurs, caractérisé en ce que lesdits moyens de mémoire sont solidaires de l'élément transducteur et sont effaçables au moins sélectivement, et en ce que lesdits moyens de commande comprennent des moyens de traitement (60) pour utiliser l'information mémorisée dans lesdits moyens de mémoire afin de modifier le signal de sortie délivré par lesdits moyens de mémoire de manière à commander la compensation desdites erreurs, lesdits moyens de traitement mettant également à jour périodiquement ladite information.

2. Système formant transducteur selon la revendication 1, dans lequel l'information de balayage concerne la position de l'élément (32) sur son trajet de balayage, et lesdits moyens de commande répondent à la position détectée par lesdits moyens de balayage (68,44,46) pour commander le déplacement de l'élément.
3. Système formant transducteur selon la revendication 2, dans lequel les erreurs du balayage exécuté par l'élément transducteur sont provoquées par une non-linéarité des moyens de détection de la position; et dans lequel lesdits moyens de mémoire (50,80) mémorisent une erreur mesurée pour lesdits moyens de détection de position, en des points sélectionnés sur ledit trajet de balayage.
4. Système formant transducteur selon la revendication 3, selon lequel lesdits moyens de commande incluent des moyens (69) pour mémoriser une table de position sélectionnée dans ledit trajet de balayage; et dans lequel lesdits moyens de traitement (60) comprennent des moyens pour utiliser les erreurs mémorisées dans lesdits moyens de mémoire (50,80) pour modifier les positions mémorisées dans ladite table.
5. Système formant transducteur selon la revendication 4, dans lequel des moyens comparateurs (73) sont prévus pour déclencher ledit élément transducteur (32), lesdits moyens comparateurs (73) comparant les signaux de sortie délivrés par lesdits moyens de mémoire (69) et par lesdits moyens de détection de

position (68).

6. Système formant transducteur selon l'une quelconque des revendications précédentes, comprenant en outre une tête (10) contenant ledit élément transducteur (32), un connecteur électrique (16) pour le raccordement de l'élément transducteur au reste du circuit (18) et un câble (12) raccordant ladite tête et ledit connecteur, et dans lequel les moyens de mémoire (50) sont montés sur le connecteur électrique (14).
7. Système formant transducteur selon l'une quelconque des revendications précédentes, dans lequel ledit élément transducteur (32) produit un signal de sortie lorsqu'il exécute son balayage, et lesdits moyens de mémoire (50,82) mémorisent une indication d'une caractéristique sélectionnée du signal de sortie délivré par ledit élément transducteur pour des conditions sélectionnées; et comprenant des moyens (70) pour utiliser les indications de la caractéristique du signal de sortie mémorisées dans lesdits moyens de mémoire pour commander la caractéristique sélectionnée du signal de sortie délivrée par ledit élément transducteur.
8. Système formant transducteur selon l'une quelconque des revendications précédentes, comprenant une indication (83) de commande des domaines d'utilisation, mémorisée dans lesdits moyens de mémoire (50,82), les moyens de traitement (60) répondant à l'indication de commande des domaines d'utilisation, pour limiter les domaines d'utilisation du transducteur.
9. Système formant transducteur selon l'une quelconque des revendications précédentes, dans lequel lesdits moyens de mémoire (50,84,86) mémorisent une information additionnelle concernant le fonctionnement dudit élément transducteur.
10. Système formant transducteur selon l'une quelconque des revendications précédentes, dans lequel l'élément transducteur (32) est un transducteur de balayage à ultrasons.
